How to take mortar samples

Mortar samples are best taken by someone with an understanding of the building, who can tell the difference between original and later repair mortars. Some knowledge of the building and its construction is helpful.

Lime mortar samples can normally be removed using hand tools such as a chisel or flathead screwdriver. Harder mortars may require the use of hammer to drive a chisel (taking care not to damage the stonework/brickwork). The aim should be to remove a 'good handful' (approx. 100g) of bonded lumps of mortar, harl or plaster, rather than loose/crumbly material.

How to package your samples

Mortar samples should be well-packaged to prevent damage in transit. Each sample supplied for analysis should be placed in a self-seal type polythene bag (available from most supermarkets, or we'll send you some upon request) or sealed rigid container (the plastic takeaway type). Each sample should be labelled with the building name/address, sample number (S1, S2, S3 etc. if more than one), and sample function (e.g. pointing, bedding, harling, plaster etc.)

The packaged samples can then be shipped in a cardboard box or padded envelope, along with this completed form. Extra padding may be required to protect the sample(s).
