The Guide

Pocket Book Reference for Truss Installation

Note

"The Guide" is intended to be used only for roof trusses supplied by accredited Multinail Truss Fabricators.

"The Guide" is intended as a guide only to the installation of Timber Roof Trusses and should only be used by properly trained and qualified staff who are competent in the installation of roof trusses.

If you have any doubts about using or interpreting "The Guide" please do not hesitate to contact your Truss Fabricator or Multinail Australia for advice and assistance.

As truss installation invariably involves working at heights, you should undertake a risk assessment for all construction sites as well as following all relevant workplace safety practices and legislative requirements.

1. Check First!

This guide is based on Australian Standard AS4440 - Installation of nailplated timber roof trusses.

Before commencing, you must check that your building falls within the limits shown in Section 2.

Before you erect trusses, you must check to ensure that they comply with the specific requirements of the job.

Special consideration is required for the support of additional loads (e.g. hot water tanks, solar water heaters, air conditioners, etc) or the construction of buildings to withstand high wind loads.

You must ensure that all the relevant information has been passed to the truss fabricator and that you use trusses only in the application for which they are intended.

Before you erect trusses, you must inform the roof truss supplier of any scaffolding, edge protection devices, anchor points, etc. with the potential to add loads to the structure at any stage of construction.

The supporting structure must be adequate to support and hold down the trusses and their associated roof, ceiling or floor loads.

You must fully understand the information contained in this guide plus any supplementary information before attempting to erect trusses.

Safety Note

A timber truss is an engineered structural component designed and manufactured for specific loading and service conditions. Timber members must not be removed (e.g. by sawing) from any part of the truss, as this may significantly reduce its structural capacity and could result in failure of the structure.

2. Check This Guide Is Applicable to Your Job

- I. Residential structures (BCA Classes 1, 2, 3 and 10) and light commercial structures.
- II. Maximum Roof Pitch of 45°.
- III. Maximum Span 16m.
- IV. Shape in plan view to be rectangular or near-rectangular, or a series or a combination of rectangular shapes or near-rectangular shapes, including splayed-end and boomerang-shaped buildings and the like, and projections such as bay windows.
- V. Maximum truss spacing of:
 - A. 900mm; or
 - B. 1200mm, for sheet metal roofs in an area of Design Wind Speed up to N3.
- VI. Maximum Design Gust Wind Speed of 74m/s Wind Classification C3 for ultimate limit state method in accordance with AS/NZS 1170.2 or AS4055.

Figure A1-03-01-03

APPLIES:

☐

(Tick)

3. Durability Notice

No galvanised nailplates should be permanently exposed to weather or other sources of moisture.

For environments where the atmosphere may be conducive to corrosion (e.g., some types of industrial and agricultural buildings, swimming pools or buildings near the ocean and subject to salt spray) consideration should be given to the use of stainless steel nailplates and fixings.

3.1 Sarking

Multinail recommends that all roofs be sarked to prevent moisture ingress into the roof space through gaps in roof tiles or as a result of condensation forming on metal roof sheeting. It is mandatory that all roofs be sarked as per recommendations in the Building Code of Australia and AS2050 "Installation of Roof Tiles" which includes but is not limited to all roofs in a wind speed area greater than N3. Refer to the tile manufacture's recommendations for further information.

4. Transport and Storage

Trusses may be transported either vertically or horizontally. Regardless of the transport orientation, all trusses must always be fully supported.

No excess from the tie-down straps or bracing should be on any part of the truss.

Trusses should be inspected on arrival at site. Any damaged trusses should be reported immediately.

Do not site repair any truss without the approval of the truss fabricator.

Bundles (or individual trusses) should be stored flat and kept dry. Gluts or packers should be placed at 3000mm maximum spacing to support the trusses off the ground.

4.1 Protection from Water

To ensure the long-term structural integrity of trusses, the trusses must be protected from exposure to water. This applies to the timber from the time prior to truss fabrication to after the time the roofing material has been installed. Failure to protect the timber from water exposure may lead to truss failure.

5. Safety on Site Using Timber Engineered Components

Floor Trusses, Wall Frames and Roof Trusses, etc. are designed to be part of a structural system that includes the battens, bracing, trusses, binders, ceiling, supporting structure and the connection of these elements. Each element on its own may not be strong, but fixed together they form a strong, stiff and stable system.

Until all these elements are fully assembled, fixed and braced, the roof structure and building will not have achieved its final strength.

To prevent possible injury to construction personnel and/or damage to the engineered components, anyone working with the engineered structural components must exercise common sense and a large degree of caution during the construction phases.

Appropriate protection of people and products should be considered at all times.

Some common sense protection items include:

- Ensure that all elements are connected to each other as designed.
- Ensure that all elements are equally braced for dead load, live load and wind load.
- Use appropriate lifting devices that do not damage existing components already installed.
- Use appropriate temporary bracing, scaffolding and planks prior to working on the engineered components.
- Do not load any truss, including standing on it, until all temporary bracing for that truss has been installed and stabilised and all girder boot fixings have been correctly fastened.
- Do not apply any load, including standing or leaning on, to the overhang of any truss especially jack and creeper trusses/rafters until the fascia is installed.
- Do not stack excessively heavy loads of materials on truss components.
- Ensure adequate bracing is firmly attached to enable the unfinished structure to support construction live loads, material and any wind loads that may occur overnight and during the day.
- Other as applicable to each job.

Since every job is different in the conditions that prevail on site, it is the builder's responsibility to ensure that these conditions are closely considered and met before, during and after construction while work is still occurring on the site, including while other trades are involved.

Note that any recommendation in this document regarding the above issues is a suggestion only and may not be applicable to every job. Additional safety measures to the above may be required to protect the workers, components and the environment.

6. Lifting

The following diagrams show the correct method of lifting and handling trusses on site. Trusses may also be pulled up to the wall top plates using skids placed approximately 3m apart.

Spans under 9m

Figure C1-02-01-01

Figure C1-02-01-02

Spans 9m to 16m

Figure C1-02-01-03

Figure C1-02-01-04

Slings should be located at equal distances from the truss centreline, and be approximately one-third to one-half truss length apart.

Safety Notes

When lifting, special care must be taken to avoid damage to truss joints. If it is necessary to handle a truss on its side, precautions must be taken to avoid damage due to sagging. Trusses must never be lifted by the apex joint only. Spreader bars (with attachment to panel points) must be used where the span exceeds 9m. For spans over 16m, contact the Multinail Engineering Department.

7. Recommendations for Temporary Bracing

This section provides temporary bracing details recommended for gable, hip and dutch-hip end roof trusses.

The first truss should be erected correctly, straight and vertical, and temporarily braced in position.

Each successive truss should then be spaced correctly and fixed back to the first truss with temporary ties to top chord at a maximum spacing of 3000mm and to bottom chord at a maximum spacing of 4000mm.

Use temporary ties as per the following table:

Minimum Size of Temporary Ties		
Truss Spacings	For Top Chords	For Bottom Chord
Up to 900mm	25 x 50 F5	35 x 70 F5
Over 900mm up to 1200mm	35 x 70 F5	35 x 70 F5

Ties should be fixed to each truss with a minimum of one 75mm x 3.05Ø nail.

Important Notes

1. Temporary ties are not designed to be a trafficable platform.
2. Steelbrace is not acceptable for temporary bracing.

7.1 Hip or Dutch Hip End Roof

Temporary bracing for a hip or dutch-hip is achieved by erecting and fixing the truncated girder, or dutch-hip girder truss, in the correct position to the top plates and bracing the girder truss back to the corner of the building as shown in the Figure below.

Ensure no weight or load is placed on the truss overhangs, especially in the vicinity of the hip overhang, until all necessary structural members, such as structural fascias and roof battens, have been fully installed.

Temporary bracing for Hip or Dutch-Hip End Roof

Figure C2-06-01-02

CHECK BRACED PROPERLY:

(Tick)

7.2 Gable-End Roof

Temporary bracing for a gable-end roof is achieved by erecting and fixing the first truss to top plates at one end of the roof and bracing the truss to a rigid element; e.g., the ground, as shown in the Figure below.

Figure C4-02-05-01

Temporary longitudinal ties to truss top chords at 3000mm centres

CHECK BRACING:

☐

(Tick)

8. Installation Tolerances

For proper truss safety and performance, trusses must be installed straight and vertical and in their correct position as specified in sections 8.1 to 8.3.

NOTE: The best method for ensuring correct truss positioning is to mark the locations on the top plate or other supporting elements in accordance with the truss layout prior to truss installation.

8.1 Bow

Trusses must be erected with minimal bow in the truss and in any chord, with a tolerance not exceeding the lesser of length of the bowed section/200 and 50mm, where length is defined in Figure C1-01-01-04 or Figure C1-01-01-05.

Figure C1-01-01-04

Top view

Side view

C1-01-01-04

Figure C1-01-01-05

Top view

Side view

C1-01-01-05

CHECK BOW:

☐

(Tick)

8.2 Plumb

Trusses must be erected so that no part of the truss is out of plumb with a tolerance not exceeding the lesser of height/50 and 50mm where the height is measured at the location under consideration (see Figure C1-01-01-03).

CHECK PLUMB:

☐

(Tick)

8.3 Spacing

Trusses must be erected at a spacing not exceeding that specified in the design specifications or truss layout.

CHECK SPACING:

☐

(Tick)

Figure C1-01-01-03

8.4 Camber

Trusses are built with a camber in the bottom chord which is intended to compensate for the long-term deflection due to dead loads. A girder truss will have more camber than other trusses.

Figure A1-02-02-10

CHECK CAMBER:

☐

(Tick)

9. Truss Laminations

9.1 Double Trusses

It is necessary that double trusses are nailed together prior to loading the roof.

In Chords: two (2) rows (staggered) of 3.05mm diameter nails at maximum 450 centres from one side, or use 1/Green Tip Screw at 600 centres.

In Webs: one (1) row of 3.05mm diameter nails at maximum 450 centres from one side. A minimum of two nails per web is required or use 1/Green Tip Screw at 600 centres.

Nail Lengths:

65mm long for up to 35mm thick laminates.

75mm long for up to 45mm thick laminates.

Special truss design fixings may be specified in excess of this.

9.2 Triple Trusses

It is necessary that triple trusses are nailed together prior to loading the roof

In Chords: Nail as for double truss from each side, and also use 1/M12 bolt at joints or 2/Green Tip Screws from each side at every web junction through the top chord, plus at the heel joint through the top chord.

If bolted brackets are used on the bottom chord at 1200mm centres or less, then these bolts are sufficient for the bottom chord.

In Webs: one (1) row of 3.05mm diameter nails at maximum 450 centres from each side. A minimum of two nails per web is required or use 1/Green Tip Screw at 600 centres.

Screw Lengths:

65mm long Green Tip Screws for up to 35mm thick laminates.

100mm long Black Tip Screws for up to 45mm thick laminates.

Special truss design fixings may be specified in excess of this.

10. Use of Gun-Nails with Multinail Products

10.1 Multinail Products that allow for gun-nail fixing

Given the benefits of the gun-nail fixing method, the following Multinail products may be fixed using 32mm x 2.5Ø hardened screw shank gun-nails complying with AS 2334-1980 or ASTM F1667-15:

- Flat Tension Bracing
- Cyclone Tie
- Uni Tie
- Stud Strap
- Nail on Stud Tie
- Joist Hanger

10.2 Limit state design capacity for gun-nail fixing method

When substituting Multinail 30mm x 2.8Ø reinforced head nails with 32mm x 2.5Ø hardened screw shank gun-nails, either the number of required nails may need to be increased to maintain the same limit state design capacity, or the limit state design capacity may be reduced to maintain the same number of nail fixings, depending on the application and product geometry. Refer to the relevant product brochure for further information.

10.3 Minimum gun-nail spacing

For Ø2.5mm gun-nails, the minimum spacing specified in AS 1720.1 must be followed unless noted otherwise:

- Timber end distance – 50mm
- Timber edge distance – 12.5mm
- Between nails, across the grain – 25mm
- Between nails, along the grain – 50mm

10.4 Installation notes

Gun-nails must not be driven through existing nail holes, as the nail heads may pull through the holes and reduce connection capacity. Instead, gun-nails must be placed at least 5mm from any metal edge or hole and spaced evenly in accordance with the minimum gun-nail spacing requirements.

Gun-nails must be driven at the appropriate pressure to ensure the nail heads sit flush with the metal surface.

Care must be taken when using gun-nails with metal products. Refer to the nail gun supplier's safety recommendations before operating these tools. Considerations include appropriate protective clothing, eye protection, and the angle of the nail gun relative to the metal. Multinail accepts no responsibility for injuries incurred through the use of nail guns when installing Multinail metal products.

For any queries regarding the use of gun-nails with Multinail products, please contact Multinail Engineering Support.

11. Truss Connection

This section specifies the minimum requirements for truss-to-truss connections. At least two 3.05Ø nails, with a penetration of 10 times the nail diameter into the supporting member, shall apply to connect each member.

Note that different connection details apply at different design wind speeds.

MY DESIGN WIND SPEED IS :

11.1 Hip End Fixing Details

Ensure no weight or load is placed on the truss overhangs, especially in the vicinity of the hip overhang, until all necessary structural members, such as structural fascias, props and roof battens, have been fully installed.

11.1.1 Hip-End Connection for Low Wind Area (Wind Classification N1, N2, N3 or C1)

Connection of jack, creeper and hip trusses at a hip-end roof for design wind classification N1, N2, N3 or C1 shall be in accordance with the details shown. These details are suitable for a maximum truncated girder station of 3600mm.

The fixing requirements for hip ends in this section are based on the design criteria that are governed by dead loads.

Figure C2-01-01-01

Note 1: For effective skew nailing, the nail shall be driven into one member not closer than 25mm to no more than 38mm from the area in contact with the adjacent member. The nail shall be driven at an angle between 30° and 45° to the face into which the nail is driven.

Note 2: Where nails are smaller than the nominated size or other than plain shank nails, or machine driven or both, their performance shall not be inferior to the nail sizes given.

Note 3: Roof battens or purlins and ceiling battens shall be fixed to trusses in accordance with the approved specification.

Note 4: Top chord details A1 and B1 also apply to GTGs (Girder Truncated Girders)

Fully Trussed Hip End Detail Low Wind (N1, N2, N3 or C1)

Notes: - Max verge overhang 1200mm - Max outrigger/truss centres 1200mm

11.5 Truss Boot Installation

Various types of truss boots can be used to form truss to truss connections. The particular boot to be used is specified by the truss fabricator for each individual joint.

Important Notes:

1. It is essential that all appropriate bolts, washers and bracing are installed correctly into close-fitting holes as soon as the truss is erected. Damage to personnel, the trusses, the truss boot or ceiling linings may result from partial installation.
2. Do not use reduced shank or cuphead bolts.
3. For bracket capacities and connection details refer to the relevant product brochure.

High Load Truss Boot

Easy Fix Girder Bracket

High Load Easy Fix Girder Bracket

12. Waling Plate Fixing Details to Dutch Hip Girders

The recommendations for waling plate depth and fixing methods have been determined based on the following criteria:

- Maximum dutch hip girder station 3600mm.
- Maximum roof pitch 35 degrees.
- Maximum truss centres 1200mm.
- Jack truss overhang plus cantilever not exceeding jack truss back span.
- Girder and waling plate to be designed using Multinail Software with a web layout similar to that selected from the following table.
- Minimum waling plate thickness to be 35mm.

Truss web layout	Maximum truss span (mm)
Queenpost	5000
A Type	8500
B Type	12000
C Type	16000

Notes:

1. The fixing method of the waling plate to the dutch hip girder will generally determine the waling plate depth. Refer to Tables 1, 2, 3 or 4 to select the waling plate depth and fixing details.
2. The truss chords **MUST** be a minimum of 90mm deep and webs a minimum of 70mm deep **UNLESS** noted otherwise in the following fixing recommendations.
3. Joint groups as shown are for **BOTH** waling plate and truss members.
4. Engineering fixings may be individually designed for other specific cases.
5. Truss webbing types and span limits above relate to the fixing of waling plates only and do not refer to the maximum load-carrying capacity of the truss itself.

13. Roof Battens

The size, spacing and fixing of roof battens or purlins shall be in accordance with the relevant code approved specifications. The batten and fixing must have adequate strength to laterally restrain the roof trusses. Fix each batten to every lamination on every truss.

In addition to providing support to the roof cladding, roof battens prevent truss top chords from buckling. The buckling action is due to the compressive force in the top chord of the roof truss. The roof battens resist this buckling action and transfer the forces to the steel roof bracing and down to the supporting structure. Each element and fixing in the sequence is essential for roof structure stability.

In areas where battens or purlins are not bound on both sides by diagonal bracing, battens shall be continuous (see Figure C1-04-01-01).

Where required, splices in battens shall be arranged so no more than one-third of battens are spliced and no two splices are adjacent in any top chord.

For more information, refer to Multinail Technical recommendations for Roof Battens.

Important note: DO NOT splice roof battens on girder trusses.

13.1 Roof Batten Splicing

The following roof batten splicing details are recommended to adequately provide lateral restraint to the roof truss top chords for all metal sheet roofs.

Batten tie down and size to be designed by others

Rules given in AS4440 must also be followed which include:

- Do not splice battens on girder trusses
- Fix each batten to every lamination on every truss with minimum 2/nails
- Adjacent battens should not be spliced at the same point
- Not more than 1 in 3 battens to be spliced on any truss top chord

Design Criteria	
Roof material	Steel Sheeting
Truss centres	1200mm maximum
Batten size	35 x 70 min. 45 x 90 maximum
Batten spacing	1200mm maximum

Option 1

Figure C1-04-02-01

Splice plates must be located centrally on the batten and centrally across the joint. Splices may be located anywhere along the batten.

Option 2

Figure C1-04-02-02

Option 3 *Figure C1-04-02-03***Option 4***Figure C1-04-02-04***Option 5***Figure C1-04-02-05*

14. Top Chord Bracing

Top Chord bracing is required.

The purpose of a top chord bracing system is to transfer the forces generated by the top chord restraints, such as roof battens or purlins, back to the supporting structure.

CHECK APPROPRIATE BRACING LAYOUT USED: ☐ (Tick)

For more information on specific roof shapes, refer to AS4440.

14.1 Steelbrace for Gable Roof

The type and layout of the top chord steelbrace relate to the span, shape and loading of the roof.

The angle from steelbrace to wall frame shall be between 30° and 45°.

Bracing bays shall extend from the end trusses of the roof, unless otherwise specified in this guide.

The area of the standard overhangs is not required to be braced.

In the following figures, length (L) and half span (h) are defined as follows:

Length (L) - the length of run of similar trusses with similar support positions. However, where adjoining sections of the roof have trusses running parallel to the trusses in the section being considered and where the top chords are in the same plane, Length (L) may be extended into the adjoining section, provided that the trusses have common support positions (see Figure C5-04-02-01).

Length (L) and Half Span (h)

The horizontal distance from the pitching point to the point at which the top pitch changes.

Figure C5-04-02-01

C5-04-02-01

Figure C5-04-02-02

C5-04-02-02

14.2 Spans Up to 8m

For spans up to 8m, the single steelbrace shall be arranged in a V-shape configuration. Each truss in the brace section shall be crossed with at least two braces.

The top chord steelbrace shall be arranged according to the following roof lengths:

Roof Length (L) Less Than Half Span (h)

See section 14.3 and Figure C5-04-04-02.

Very short roof

Where the roof Length (L) is 1 to 1.5 times the half span (h) of the roof truss, the steelbrace shall be arranged as shown.

Steelbrace Layout Roof, Spans Up to 8m

Figure C5-04-03-01

Steelbrace Layout for Very Long Roof, Spans Up to 8m

Where the roof Length (L) is more than 4 times the half span (h) of the roof truss, the steelbrace shall be arranged as shown.

Figure C5-04-03-04

C5-04-03-04

14.3 Spans of 8m to 13m

For spans of 8m to 13m, a steelbrace in an X-shape configuration shall be used.

A single steelbrace shall be used with the limitation in the span of roof trusses as specified in table below.

Each truss in the brace section shall be crossed with at least four braces.

For a roof with overall span greater than the maximum values specified in Table 1 but less than 13.0m, a double steelbrace shall be used, as shown.

Maximum Overall Truss Span for Single Steelbrace (In Metres)

Wind classification	Roof pitch <15°	Roof pitch 15° to 20°	Roof pitch 20°+ to 30°	Roof pitch 30°+ to 35°	Roof pitch 35°+ to 45°
N1-N3, C1	13.0	13.0	12.5	11.5	9.5
up to N4, C2	13.0	13.0	10.5	9.5	8.0
C3	12.0	11.0	8.5	Not suitable	Not suitable

Figure C5-04-04-06

C5-04-04-06

The top chord steelbrace for spans of 8m to 13m shall be arranged according to the following roof lengths:

Steelbrace Layout for Very Short Roof, Spans 8m to 13m

Where the roof Length (L) is very short compared to the half span (h) of the roof truss such that it would result in a brace angle greater than 45° , a diagonal steelbrace arrangement shall be required each side of the ridge line as shown. Bracing bays shall be spaced across the roof such that the brace angle is always between 30° and 45° .

Figure C5-04-04-02

Figure C5-04-04-07

C5-04-04-07

Steelbrace Layout for Short Roof, Spans 8m to 13m

Where the roof Length (L) is 1.5 to 3.5 times the half span (h) of the roof truss, the steelbrace shall be arranged as shown.

Figure C5-04-04-08

C5-04-04-02

C5-04-04-08

Steelbrace Layout for Long Roof, Spans 8m to 13m

Where the roof Length (L) is long compared to the half span (h) of the roof truss such that it would result in a brace angle less than 30° , two or more crossed bracing bays shall be required each side of the ridge line to ensure the brace angle is between 30° and 45° (See Figure C5-04-04-04).

Figure C5-04-04-04

Steelbrace Layout for Very Long Roof, Spans 8m to 13m

For a very long roof the steelbrace is continued for the length of building such that each truss shall be crossed with at least four braces (see Figure C5-04-04-05).

Figure C5-04-04-05

14.4 Spans of 13m to 16m

For truss spans of 13m to 16m, the steelbrace shall be in an X-shape configuration over the whole roof with an additional braced bay at each end and intermediate braced bays at maximum 13000mm centres, as shown.

Steelbrace Layout for Very Long Roof, Spans 13m to 16m

Figure C5-04-05-01

Maximum overall truss spans for steelbrace

Maximum overall truss span, m							
Wind	Roof Pitch						
	Single brace		Double brace				
	<15°	15° to 20°	<15°	15° to 20°	20° to 30°	30° to 35°	35° to 45°
N1-N3, C1	16.0	16.0	16.0	16.0	16.0	16.0	13.5
N4, C2	15.5	13.0	16.0	16.0	14.5	13.5	N/S
C3	Not suitable	Not suitable	16.0	15.5	Not suitable	Not suitable	Not suitable

14.5 Steelbrace for Hip roof

14.5.1 Bracing Requirement for Standard Trusses

For roofs on buildings of rectangular plan with trussed hip ends or dutch-hip ends, the steelbrace for standard trusses shall be required between the apex of hip ends only.

In such cases the roof Length (L) shall be taken as being the distance between the two intersections of hip and ridge line at each end of the building.

One of the criteria from section 14.2 to 14.4 shall then be applied as shown.

Steelbrace Layout for Standard Trusses of Hip Roof

Figure C5-04-07-01

14.6 Bracing Requirement for Jack Trusses

For standard roof trusses less than 13m, no bracing to jack trusses is required.

For standard truss spans of 13m to 16m, the single steelbrace shall be arranged in an X-shape configuration. The angle from steelbrace to end wall shall be between 30° and 45° .

The top chord steelbrace for jack trusses shall be arranged in accordance with the following:

Where the Horizontal Top Chord Length (HTL) is less than the Truncated Girder Station (TGS), the steelbrace shall be arranged as shown.

Steelbrace Layout for Jack Trusses (HTL < TGS)

Figure C5-04-08-01

Figure C5-04-08-04

Steelbrace Layout for Jack Trusses (HTL = 1 to 1.5 TGS)

Where the Horizontal Top Chord Length (HTL) is 1 to 1.5 times the Truncated Girder Station (TGS), the steelbrace shall be arranged as shown.

Figure C5-04-08-02

**Steelbrace Layout for Jack Trusses (HTL > 1.5 x TGS)**

Where the Horizontal Top Chord Length (HTL) is longer than 1.5 times the Truncated Girder Station (TGS), the steelbrace shall be arranged as shown.

Figure C5-04-08-03

14.7 Steelbrace for Dual-Pitched Roof

On dual-pitched or cut-off roofs where the ridge line is not central on the building, each side of the ridge shall be considered as a separate case.

A steelbrace layout resulting from a combination of the criteria specified in Clauses 14.2 to 14.7 shall apply.

Typical Steelbrace Layout for Dual Pitched or Cutoff Roof

Figure C5-04-09-01

C5-04-09-01

Figure C5-04-09-02

C5-04-09-02

14.8 Steelbrace for Bell Roof

The steelbrace shall be spliced at bell breaks, see Figure below for splicing details.

Figure C5-04-10-01

Figure C5-04-10-02

14.9 Steelbrace for Mono-Pitched Roof

Where the roof consists of half trusses (mono-pitched roof), the span of the half truss shall be taken as the half span (h), and one criterion from Sections 14.2 to 14.4 shall be applied.

The apex of the half truss shall be braced to the supporting structure with diagonal bracing in the vertical plane as specified for half truss fixing for apex bracing in Figure C5-04-12-08 and Figure C5-04-12-09.

14.10 Fixing of Steelbrace

The steelbrace shall be arranged in a V-shape or X-shape configuration over the top of the top chords as specified in the bracing layouts in Clauses 14.2 to 14.4. Steelbrace shall be fixed to each truss in the brace section and to the supports, using a minimum of 30mm x 2.8Ø reinforced-head nails in accordance with the following details:

15. Bottom Chord Bracing

A permanent bottom chord bracing system is required to restrain truss bottom chords against lateral buckling under wind uplift. A direct fixed or battened ceiling is generally sufficient to perform this function except as noted in section 15.2 below.

15.1 Ceiling Battens

Batten spacing shall not exceed that specified by the approved specifications for ceiling support and bottom chord restraint centres.

15.2 Bottom Chord Ties

For suspended ceilings, or exposed bottom chords, or where ceiling battens do not provide restraint to bottom chords (e.g. metal furring channels clipped to trusses) the size and spacing of separate bottom chord ties shall comply with the approved specifications.

Notes:

1. The bottom chord ties are not intended to replace the binders required to support the end wall.
2. The bottom chord ties and bracing are intended only to restrain (i.e. to stop from buckling) truss bottom chords and do not provide lateral stability to the building to resist lateral wind loads.
3. Buildings with suspended ceilings require additional bracing to ensure the lateral stability of the walls. **The responsibility for the stability of the structure rests solely with the project engineer/building designer.**
4. These bottom chord ties are not designed to be a trafficable platform.

For trusses with ceiling directly fixed to truss bottom chords by glue or nails, or both, ties as temporary bracing to bottom chords are required until the ceiling is fully fixed in place. See section 7 for details.

Where bottom chord ties are required, they shall be braced or fixed to a building element such as supporting walls, which in turn can transfer these bracing loads to the structure.

Steelbrace shall be at approximately 45° to wall top plates, see Figure below, and shall be fixed to each truss and to the wall in the same manner as for top chord brace fixing.

Typical Bottom Chord Ties Bracing Layout

Figure C5-04-13-01

Figure C5-04-13-02

Figure C5-04-13-04

Figure C5-04-13-03

CHECK: ☐ (Tick)

16. Web Bracing

Where truss designs require bracing to be applied to webs, this can be achieved by the use of longitudinal ties, T-stiffeners or other supplementary members. Where longitudinal ties are used, they shall be a minimum of 70mm x 35mm F5, or as specified in the design specifications. The web ties shall be fixed to the web of each truss at even spacing of the web with two 75mm x 3.05Ø long nails and braced to the truss with one bay of crossed steelbrace at each end and an intermediate bay at 10m centres. Web ties shall be continuous or, where required, spliced by lapping over at least two adjacent trusses.

Figure C5-04-14-01

CHECK:

☐

(Tick)

17. Walls

Trusses are usually designed to be supported only by the outer walls of the structure with none of the loadbearing transmitted to internal walls.

The bottom chord of the truss is designed with an inbuilt camber to suit the span and load. This camber is progressively taken up as the load is applied (i.e., the roofing and ceiling).

Wall frames of non-loadbearing internal walls must therefore be constructed to allow free movement of the trusses as they are loaded and unless otherwise specified a truss must not be supported at any intermediate point along its span.

17.1 Non-Loadbearing Walls

Non-loadbearing walls must comply with the requirements specified in the relevant Standards as appropriate to the material.

Non-loadbearing walls, as designated, shall not carry any truss loading and shall not be packed to touch the underside of trusses, see Figure below.

NOTE: One way to ensure non-loadbearing is to set the non-loadbearing walls at a lower level than the loadbearing walls. The recommended difference in level is the ceiling batten depth (if any) plus 10mm minimum.

Figure A1-03-01-02

CHECK:

☐

(Tick)

17.1.1 Fixing to Top Plates of Non-Loadbearing Walls

The requirements for fixing of timber trusses to the top plates of non-loadbearing walls shall be in accordance with the following wall designations:

(a) Non-Bracing Wall: Where a non-loadbearing wall is stable in its own right, no stabilizing fixing is required.

(b) Bracing Wall: Where a freestanding non-loadbearing wall is designated as a bracing unit in accordance with AS 1684.2 or AS 1684.3, the timber trusses shall be fixed to the top plate of the wall in such a way that the bottom chord of the truss is restrained horizontally but allows for deflection when the truss is loaded. The Figure below gives an example of the fixing details.

Wall is Parallel to Truss

Wall is Perpendicular to Truss

17.1.2 Internal Wall Brackets

Internal Wall Brackets are used to connect internal non-loadbearing walls to roof trusses at a maximum 1800mm centres. To enable the roof truss to deflect under loads, nails to the truss must be installed at the top of the slotted holes and not hammered home to allow a loose fit only.

17.2 Loadbearing Walls

Loadbearing walls must be constructed so as to support all loads from the roof structure.

Connections to loadbearing walls are generally provided with the project documentation.

Loadbearing walls shall comply with the requirements specified in the relevant standards, as appropriate to the material, and shall not be lower than the non-loadbearing walls when trusses are supporting a level ceiling.

17.3 Bearing Plates

Under high concentrated loads from girder truss bearing plates are used to spread the load on a top plate which reduces crushing.

6mm Bearing Plate

17.4 Steel Nogs

Lighter and easier to handle, reducing the weight of frames by removing timber nogs.

Better accessibility, making it easier to run electrical wires and plumbing in wall cavity area.

Used in replacement of traditional timber nogs

G09-07-00-03

G09-07-00-04

Short Wall Bracing

Steel Nogs installed with flat tension bracing

Steel Nogs are allowed to be used with flat tension bracing

18. Parallel Chord Trusses

18.1 Correct Orientation

MultiStrut Joist, SteelWood Joist, Span Joist and EcoJoist are specifically designed with a top and a bottom. The top and bottom must be correctly positioned during installation to ensure structural integrity is maintained.

MultiStrut

Other possible orientation

18.2 Bracing

Refer to the **related truss and frame manufacturer's drawing** for the minimum number of bracing elements and no more than 1800mm crs for Type 1, or 2400mm for Type 2

In all cases, the joist bracing elements shall be distributed as evenly as possible throughout the house, to transfer the lateral wind force down to the lower storey or foundation.

If in doubt, please contact Multinail Engineering.

Type 2 Bracing Element - Bracing panel construction

Figure E5-05-02-04

Figure E5-05-02-05

18.3 Strongbacks

Strongbacks are installed within the MultiStrut Joist, SteelWood Joist, Span Joist and EcoJoist at right angles to the direction of the joists and are used to dampen vibrations by increasing the stiffness of the floor system and reducing deflection by load sharing.

Strongbacks must be fixed to the vertical webs in each MultiStrut Joist, SteelWood Joist, Span Joist and EcoJoist with 3/3.05 x 75mm nails.

Strongbacks can be located either to the underside of the top chord or sit on the bottom chord.
